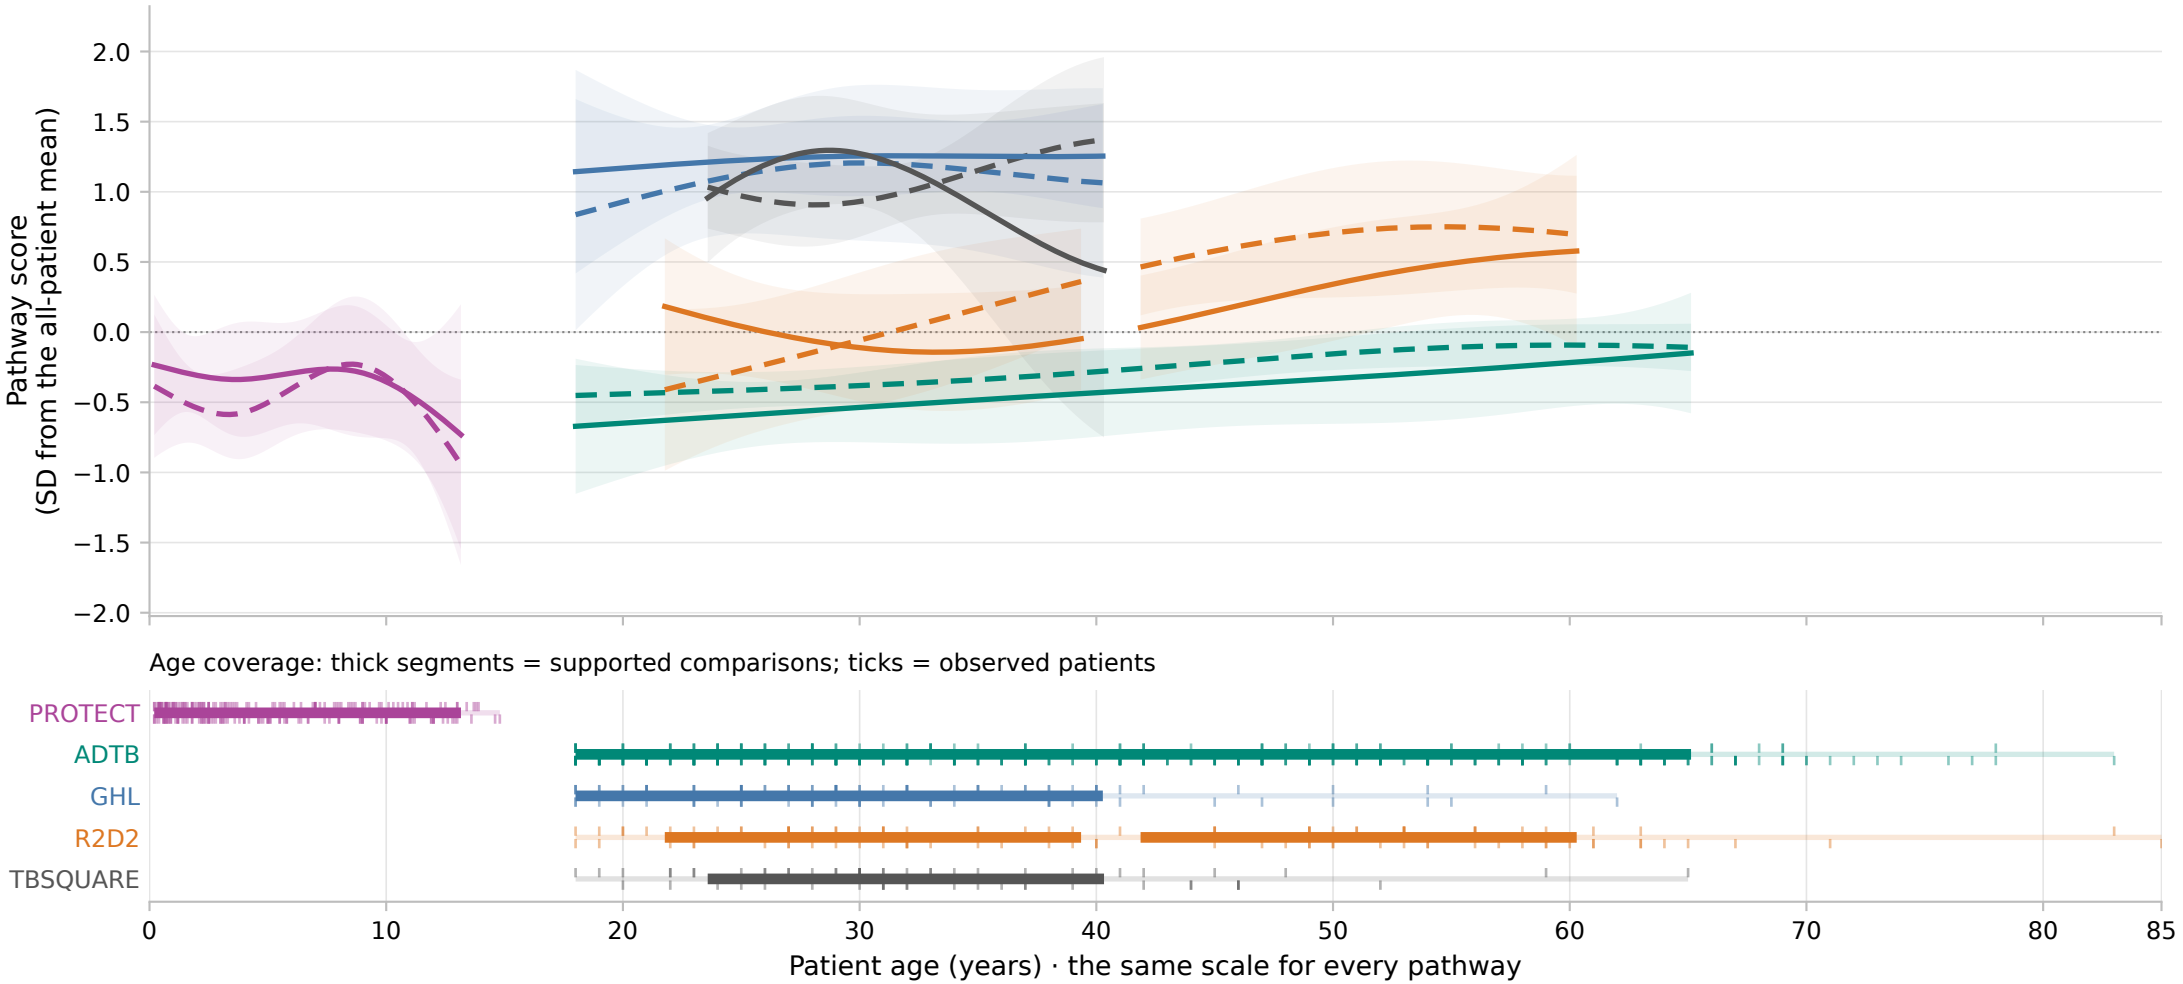
Hypoxia across age

One shared age axis · separate adjusted curves for each study

PROTECT ADTB GHL R2D2 TBSQUARE TB: solid nonTB: dashed

Age-varying TB difference: 0/5 studies at FDR < 0.05. Visible bends alone do not establish an age effect.



Age coverage: thick segments = supported comparisons; ticks = observed patients

Color = study. Solid = TB; dashed = nonTB. Pale ribbons = pointwise 95% confidence intervals.
Blank segments lack enough support for a TB–nonTB comparison. Each study retains its own clinical mix.
Different people at different ages: these curves do not follow patients as they grow older.
